# Preface

On the demand side, final energy demand increased by 4.8 percent, from 41,476 ktoe in 2010 to 43,455 ktoe in 2011. This increase in final energy demand was mainly attributed to the non-energy sector which consumed about 14.7 percent of the total final energy demand.

Despite the challenging international economic environment in 2011, the Malaysian economy recorded a steady growth rate of 5.1 percent (2010: 7.4 percent). Primary energy supply correspondingly recorded an increase of 3.2 percent from 76,809 ktoe in 2010 to 79,289 ktoe in 2011. The supply of crude oil and petroleum products, which increased by 7.7 percent, was the major contributor to the increase in the primary energy supply. Nevertheless, natural gas, with 45.1 percent share of the total primary energy supply, remained the dominant fuel in the country's energy supply mix.

On the demand side, final energy demand increased by 4.8 percent, from 41,476 ktoe in 2010 to 43,455 ktoe in 2011. This increase in final energy demand was mainly attributed to the non-energy sector which consumed about 14.7 percent of the total final energy demand.

In the power sector, coal overtook natural gas as the fuel with the biggest share of energy input for electricity generation, at 46.6 percent of the total input of 27,924 ktoe. Natural gas decreased its share to 39.3 percent compared to 45.6 percent in 2010. Hydro contributed 6.6 percent, an increase from its share in 2010 of 5.7 percent. The share of fuel oil and diesel increased significantly to 7.5 percent when compared to the previous year's share of only 1.9 percent.

Industrial energy intensity increased by 6.7 percent from 57.2 toe/RM million of GDP in 2010 to 61.1 toe/RM million of GDP in 2011. Malaysia's final energy intensity improved from 61.3 toe/RM million in 2010 to 61.1 toe/RM million, equivalent to a reduction of 0.3 percent.

The National Energy Balance (NEB) report shows that, generally over the years, Malaysia's demand for energy has been rising with our economic growth, although our final energy intensity has improved since 2002. In addressing this increasing energy demand challenge, more market-based mechanisms need to be introduced to incentivise optimal resource allocation as well as further improve energy efficiency and supply security.

Reliable monitoring and projection of energy supply and consumption by the government and industry becomes indispensable for sound decision making. In this regard, accurate and timely national energy statistics of the NEB report is indeed the foundation for developing sound national energy policies. They will enable us to initiate and implement relevant and timely policy initiatives to meet our future energy demand requirements.

I wish to thank all relevant government agencies, power utilities, independent power producers, oil and gas companies, coal producers, cement and iron and steel manufacturers, and others, for your continuing support in the publication of the NEB.

Thank you.

Minister of Energy, Green Technology and Water  
Malaysia

# Introduction

This 2<sup>nd</sup> publication of the National Energy Balance (NEB) report by the Energy Commission (ST) is a reflection of the added responsibility of being the main reference point for energy data in Malaysia apart from its roles as the nation's regulator of electricity and piped gas supplies. This report is a complete statistical publication for energy supply and demand of the nation, and is based on an energy balance format using similar energy units for all the reported data.

The NEB provides not only historical and statistical data on energy supply and demand, but also has energy indicators which show the performance of the energy sector in the country. The report covers three major areas, namely the Energy Supply, Transformation and Final Use, and includes natural gas, crude oil, petroleum products, coal and coke, electricity, hydropower and renewable energy.

As the focal point for energy data for Malaysia, ST has made collaborative arrangements, to provide monthly, quarterly and annual energy data to the relevant agencies such as the International Energy Agency (IEA), International Energy Forum Secretariat (IEFS), The Institute of Energy Economics, Japan (IEEJ), Asia Pacific Economic Cooperation (APEC) and ASEAN Centre for Energy (ACE). Additionally, ST also contributes annually to the ASEAN Energy Outlook Report, which is jointly prepared under Energy Supply Security Planning for ASEAN (ESSPA), an area of cooperation between IEEJ and ACE.

To ensure accurate, reliable and up-to-date data for the policy makers and other stakeholders of the energy sector, ST has undertaken various efforts towards strengthening relationships with data providers as it will be important to get their cooperation. Activities such as workshops, dialogue sessions and site visits have been regularly conducted with these entities, to identify and resolve issues pertaining to the gathering of energy data and statistics.

In this publication, efforts have been made to enhance the NEB coverage and scope by putting in renewable energy sources and presenting energy consumption by subsectors. Also included is data for biodiesel used in the transport sector.

The public can access the Malaysian Energy Information Hub (MEIH) to obtain historical data of energy demand and supply from 1978 till the present. The data can be downloaded in PDF or Excel format.

In 2013, we hope to integrate the data input system in the MEIH website, so as to enable all data providers of NEB to submit the data online through the MEIH website. This will improve data accuracy by minimising human error during the process of data entry by data providers.

I wish to express our gratitude to the Ministry of Energy, Green Technology and Water and all data providers for their support and contributions towards the preparation of this NEB report.

Thank you.

**TAN SRI DATUK DR. AHMAD TAJUDDIN BIN ALI**

Chairman of Energy Commission  
Malaysia

# Data Compilation

The first stage in compiling the overall balance is to rearrange the data to fit into a standard structure of commodity (or partial) balance. The commodity balance shows clearly the production, imports, exports, stock change and demand for each energy commodity. The basic sequence adhered to in the overall balance is:-

---

## **Production + Imports - Exports +/- Stock change = Apparent inland deliveries (or consumption)**

---

In practice, however, “Apparent inland deliveries” deduced from supply statistics hardly ever match actual sales data. It is necessary, therefore, to include two “statistical discrepancies” - the first to account for the difference in apparent inland delivery of primary supply mainly due to the difficulties in obtaining actual stock change data and difference in data compilation at source and the second to account for the difference in secondary supply as the result of the transformation processes of one form of energy to another.

In addition, the statistical discrepancy also acts as a balancing tool to minimize possible errors. In the case of oil and oil products, losses in transportation and distribution, as well as statistical errors are included in the statistical discrepancy. However, for electricity, distribution losses and the sector’s own use of electricity are accounted for in the “losses and own use”.

Stock changes are not fully accounted for in the balance. It is extremely difficult to obtain stocks of all energy commodities at distributors and final users. Only oil companies’ stocks were readily available and these would include stocks at refineries and depots. The statistical discrepancy might thus also include unrecorded stock changes. Coal stocks at TNB power stations and a producer in Sarawak are taken into account.

In summary, the flow of energy is represented by the following equations:-

---

## **Primary Energy Supply = Production + Imports - Exports - Bunkers +/- Stock Change**

---

<b>Energy Demand</b>	= Gross inland consumption = Final energy consumption + Consumption of the energy transformation sector + Distribution losses + Non-energy consumption
----------------------	--

# Executive Summary

## Energy Overview

The Malaysian economy recorded a steady pace of growth of 5.1 percent in 2011, despite the challenging international economic environment. Growth was lower in the first half of the year, particularly in the second quarter, as the economy was affected by the overall weakness in the advanced economies and the disruptions in the global manufacturing supply chain arising from the natural disaster in Japan. Although the global economic environment became increasingly more challenging and uncertain in the second half of the year, Malaysia's economic growth improved due to stronger domestic demand.

With the positive and strong economic growth, Malaysia's energy supply and demand also rose in tandem. Total primary energy supply and final energy demand recorded a growth of 3.2 percent and 4.8 percent respectively when compared with that of the previous year. The lower growth rates of final energy demand compared with GDP indicates that Malaysia used energy more efficiently.

## Primary Energy Supply

The Malaysian total primary energy supply in 2011 was recorded at 79,289 ktoe, a 3.2 percent growth from the previous year (2010: 3.0 percent). The growth was attributed to the higher imports of energy in order to meet local demand. The highest increase of imports was observed for natural gas as it recorded an increase of 26.3 percent to settle at 6,979 ktoe. The total increase of primary energy supply was attributed to the lower total exports of energy, as it declined by 6.6 percent to settle at 49,142 ktoe. This high drop was due to the lower export of crude oil which declined by 33.4 percent in 2011 compared to that in the previous year to register at 11,404 ktoe.

In 2011, the total crude oil and condensates production posted a decrease of 1.8 percent from that of 2010 to 28,325 ktoe or 569.8 thousand barrels per day. This was due to major scheduled maintenance and shutdown programmes that were carried out during this period, involving over 70 fields and 10 pipelines. These shutdowns were planned to coincide with tie-in work for new field development facilities that are expected to come on-stream in the next few years. Natural gas production

remained stable, averaging at 7,299 million standard cubic feet per day (mmscf/d) compared to 7,476 mmscf/d in the previous year. A slight decrease was recorded for Peninsular Malaysia and Sabah with 13.2 percent and 3.2 percent negative growth rates respectively. Overall, the production of oil and gas was maintained by the addition of three new gas fields (Cilipadi, F9 and Melor & Laho) and three new oil fields (Dana, East Piatu and Sepat) that were brought on-stream in 2011. This increased the total number of producing fields in Malaysia to 124, comprising 76 oil fields and 48 gas fields.

The primary supply of crude oil was at 24,679 ktoe in 2011, an increase of 9.7 percent from 22,487 ktoe in 2010. The increase was mainly due to higher imports and lower exports during the 2011 period. The primary supply of natural gas which stood at 35,740 ktoe in 2011 is an increase of 0.8 percent from the 2010 level of 35,447 ktoe. The increase was mainly due to higher imports of natural gas in 2010. The primary supply of coal and coke in the country was stable at 14,772 ktoe in 2011 compared to 14,777 ktoe in 2010. Higher imports of coal and coke in 2011, which increased by 5.5 percent, was recorded in line with the increase in local demand especially from the power sector. In 2011, the primary supply of hydropower energy recorded an increase of 17.3 percent to 1,850 ktoe. This was due to the commissioning of Bakun Hydro that generated 300 MW in 3Q 2011 and 750 MW in 4Q 2011.

As of 1<sup>st</sup> January 2011, Malaysia's crude oil reserves stood at 5.858 billion barrels compared to 5.799 billion barrels in the previous year. This increase was due mainly from Peninsular Malaysia totalling 2.374 billion barrels compared to that in the previous year at 2.061 billion barrels. Meanwhile, as of 1<sup>st</sup> January 2011, Malaysia's natural gas reserves increased to 89.988 trillion standard cubic feet (tscf), from the 2010 level of 88.587 tscf. PETRONAS made two gas discoveries in the shallow water areas offshore of the west coast of Sabah. The first discovery was via the Zuhul East-1 well, which is located in the Samarang Asam Paya Block about 130 km southwest of Kota Kinabalu. The well was spudded in at a water depth of 38 m and reached a total depth of 2,336 m to confirm the presence of significant gas-bearing reservoirs. The current estimate of gas-initially-in-place is about 550 billion standard cubic feet (bscf).

## Energy Transformation

The total oil refineries production in 2011 was recorded at 23,867 ktoe, an increase of 12.5 percent compared to the previous year (2010: 21,207 ktoe). All major petroleum products showed an upward trend except for Petrol, LPG and Kerosene. Of the total production, Diesel took up the highest share (37.4 percent), followed by Non-Energy (19.1 percent), Petrol (15.1 percent), ATF and AV GAS (14.5 percent), Refinery Gas (6.9 percent), LPG (2.8 percent), Fuel Oil (2.4 percent) and Kerosene (1.8 percent). Currently, Malaysia's total refinery capacity is 492 thousand barrels per day, excluding the condensates splitter capacity of 74.3 thousand barrels per day.

Liquefied Petroleum Gas (LPG) production from the Gas Processing Plant (GPP) increased to 2,434 ktoe compared to the previous level of 2,299 ktoe. The LPG production from the Liquefied Natural Gas (LNG) plants recorded a more than double drop to 214 ktoe in 2011 compared to the previous year's level of 451 ktoe. The Middle Distillate Synthesis (MDS) plant output also showed a downward trend of 20.9 percent to settle at 359 ktoe compared to the previous year's level of 454 ktoe. The petroleum products from MDS plant consisted of 70.2 percent Non-Energy products, 20.6 percent Diesel and 9.2 percent Kerosene.

## Electricity

Malaysia's total installed electricity generation capacity as of 31<sup>st</sup> December 2011 was at 28,749 MW. Peninsular Malaysia had about 84.3 percent of the total, followed by Sarawak at 9.0 percent and Sabah at 6.7 percent. An additional 750 MW of major hydro capacities were recorded for 2011 in Sarawak. Gross electricity generation registered 123,561 GWh, an increase of 14.2 percent from the previous year (2010: 108,175 GWh). The electricity consumption was 107,330 GWh, an increase of 2.7 percent from the previous year (2010: 104,521 GWh). The peak demand for Peninsular Malaysia of 15,476 MW was recorded in the second quarter of the year (2Q 2011), while in Sarawak it was at 1,214 MW (in 3Q 2011) and in Sabah it was at 830 MW (2Q 2011). The calculated reserve margin for Peninsular Malaysia was 37.0 percent, 66.8 percent for Sarawak and 40.7 percent for Sabah.

In 2011, the total energy or fuel input to power stations increased by 0.8 percent to 27,924 ktoe. The biggest drop was

observed for Natural Gas, as it decreased by 13.1 percent from the 2010 level at 12,628 ktoe to 10,977 ktoe in 2011. In order to meet the local demand, the power industry shifted to diesel and fuel oil. As a result, Fuel Oil and Diesel inputs in power station increased significantly by 782.4 percent and 136.4 percent respectively. Analysis by fuel share showed that Coal and Coke are the main fuel sources for electricity generation with 46.6 percent of the total fuel inputs, followed by Natural Gas at 39.3 percent, Hydropower at 6.6 percent, Fuel Oil at 4.0 percent and Diesel at 3.5 percent.

The total electricity consumption in the country remained robust with a growth rate of 2.7 percent. The agriculture sector showed the highest growth with 9.6 percent, followed by commercial at 4.8 percent and the remaining residential and industrial sectors both grew at 1.7 percent. The industrial sector was the main consumer of electricity in Malaysia with its share of 43.9 percent of the total consumption in 2011. This was followed by the commercial sector at 34.3 percent, residential sector at 21.4 percent, agriculture sector at 0.3 percent and transport sector at 0.2 percent.

## Final Energy Demand

Total final energy demand in 2011 experienced an increase of 4.8 percent from the previous year to register at 43,455 ktoe. The increase was attributed to the high demand from the non-energy sector which grew 72.5 percent to settle at 6,377 ktoe. This was followed by the residential sector's demand growth of 4.2 percent. Demand from the transport sector also increased in 2011 by 1.4 percent to 17,070 ktoe. Analysis showed that the transport sector was still the main consumer of energy in the country with a share of 39.3 percent. This was followed by the industrial sector at 27.8 percent, non-energy sector at 14.7 percent, commercial sector at 9.7 percent, residential sector at 6.4 percent and the agriculture sector at 2.1 percent.

In 2011, the industrial GDP of Malaysia registered a positive growth of 2.7 percent compared to the previous year, with growth mainly coming from the manufacturing and construction sectors. In terms of energy efficiency, Malaysia's industrial energy intensity for 2011 was 61.3 toe/RM million, an increase of 6.7 percent from the previous year's intensity.

The total final energy demand by type of fuels shows that Petroleum Products constituted about 55.1 percent of total

energy demand, followed by Electricity at 21.3 percent, Natural Gas at 19.6 percent and Coal and Coke at 4.0 percent. All fuels experienced demand growth in 2011, except for Coal and Coke and total Petroleum Products. Natural Gas demand recorded the highest growth rate with 36.2 percent, followed by Electricity at 2.7 percent growth. Coal and Coke final demand decreased by 3.7 percent to 1,759 ktoe. Total demand for Petroleum Products also experienced a similar trend with a negative growth rate of 1.9 percent to register at 23,946 ktoe.

## Final Demand for Petroleum Products

In 2011, the total final energy demand for Petroleum Products declined by 2.0 percent with the major drop coming from the Petrol and Fuel Oil. Final demand for Petrol dropped by 14.7 percent whilst demand for Fuel Oil and LPG decreased by 13.4 percent and 1.0 percent respectively. In terms of share, Diesel (36.4 percent) and Petrol (34.1 percent) continued to be the largest contributors to the total demand for Petroleum Products. This was followed by LPG (12.1 percent), ATF and AV GAS (10.7 percent), Non-Energy (4.9 percent), Fuel Oil (1.7 percent) and Kerosene (0.1 percent).

## Outlook in 2012

Amid the more challenging external environment, Malaysia's economy is projected to experience a steady pace of growth of 4 – 5 percent in 2012. Domestic demand is expected to remain resilient and will continue to be the anchor for growth. The global oil and gas sector is expected to remain exciting in 2012, driven by dynamic business drivers such as oil price, energy demand outlook, global economic recovery and geopolitical uncertainties. Global oil demand is still projected to grow at a revised rate of 1.2 percent in 2012 compared to 1.5 percent in 2011. This downward revision is primarily attributed to weaker demand from Europe as well as higher oil prices. The majority of global oil demand growth will be from the emerging economies, with China contributing 25 percent of this growth in 2012. As for the power sector, the Government in 2011 passed the Renewable Energy (RE) Act, and launched a roadmap to increase the contribution of RE to the electricity generation mix from less than 1 percent currently to 5.5 percent by 2015. Under the Act, a Feed-in Tariff (FiT) mechanism will be implemented in December 2011, to be paid for by contributions of 1 percent of consumer electricity bills into an RE fund.

A large industrial facility, likely an oil refinery or port, is silhouetted against a bright sunset. The structures include tall cranes and large cylindrical tanks. Their reflections are clearly visible in the calm water in front of the facility.

Source:  
TNB, SESB, SEB and IPPs

Note (\*) : Most diesel units in SESB are aged sets hence they are derated due to thermal limitations.  
However, during operational state, some generating units are not available due to maintenance outages as well as random breakdowns; the actual operation capacity available to system operation for dispatch was very limited.

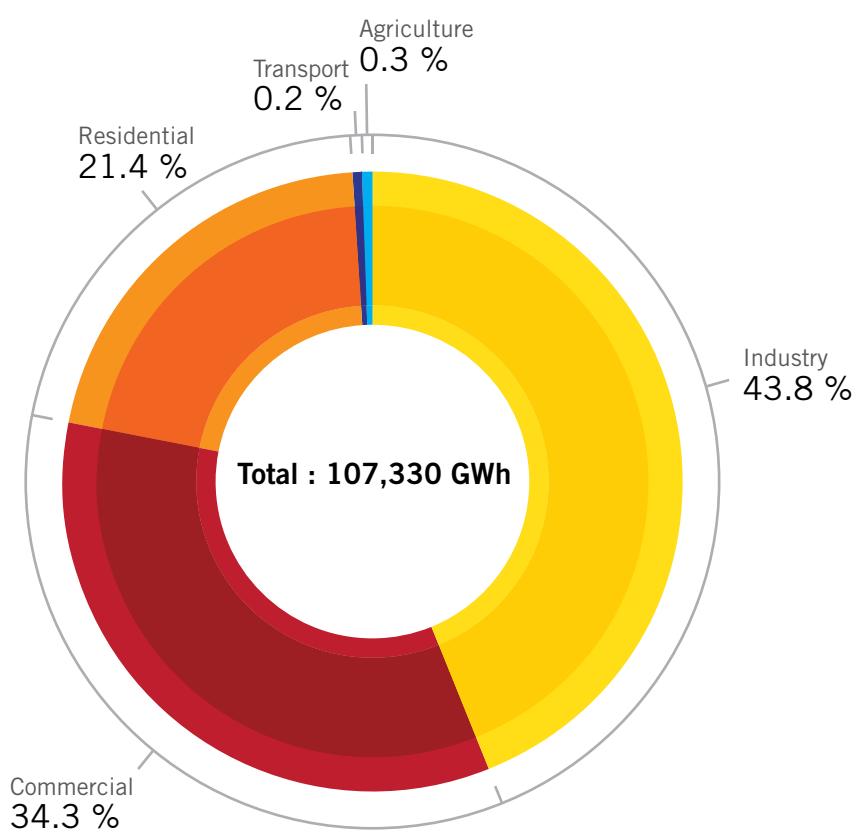

(\*\*) : Available Capacity for Peninsular Malaysia was based on Tested Annual Available Capacity (TAAC), Available Capacity for Sabah was based on Dependable Capacity.

1/ Crude production includes Condensates comprising Pentane and Heavier Hydrocarbons.

2/ Others Refer to Non-Crude Energy Forms (consist of Imported Light Diesel, Stop Residues, Crude Residuum &amp; Middle East Residue) which are used as refinery intake.

3/ GPP-LPG Extracts Liquid Products (i.e. Condensates, Ethane, Butane and Propane from Natural Gas. Ethane is not included under LPG production).

4/ Butane and Propane as M/F/E feedstocks are presented as Non-Energy use under LPG column.

5/ Estimated figures based from the Energy Commission, Statistics of Electricity Supply Industry in Malaysia 2011.

Note : Total may not necessarily add up due to rounding.

1/ Crude production includes condensates comprising pentane and heavier hydrocarbons.

2/ Others refer to non-crude energy forms (consist of imported light diesel, stop, reprox, crude residue &amp; middle east residue) which are used as refinery intake.

3/ GPP-LPG extracts liquid products i.e. condensates, ethane, butane and propane from natural gas. Ethane is not included under LPG production.

4/ Butane and propane as MTBE feedstocks are presented as non-energy use under LPG column.

5/ Estimated figures based from the Electricity Commission, Statistics of Electricity Supply Industry in Malaysia 2011.

Note : Total may not necessarily add up due to rounding.

# Notes on Energy Balance

The net calorific value (NCV) is chosen as the basis of calculations rather than the gross calorific value (GCV). Joule is used as the rigorous accounting unit, while the “tonne oil equivalent” (1 toe = 41.84 Gigajoules) is chosen as the final unit for presentation in the Energy Balance.

## Energy Balance Format

The rows of the Energy Balance tables contain the following items:

<b>Primary supply</b>	refers to supply of energy that has not undergone the transformations / conversion process within the country.
<b>Primary production (1)</b>	refers to the quantity of fuels extracted. Data for natural gas excludes the amount of reinjected and flared gas. Gross production of hydro is shown in conventional fuel equipment input.
<b>Gas Flaring, Reinjection &amp; Use (2)</b>	refers to the quantity of gas flared, re-injected into the gas fields and use for production purpose.
<b>Imports (3) and exports (4)</b>	refer to the amount of primary and secondary energy obtained from, or supplied to other countries. In the energy balance format, imports always carry a positive and export a negative sign.
<b>Bunkers (5)</b>	refer to the amount of fuels delivered to ocean-going ships of all flags engaged in international traffic.
<b>Stock change (6)</b>	refers to the difference between the amounts of fuel in stocks at the beginning and end of year and should ideally cover producers, importers and industrial consumers. At this stage, however, only oil companies' stocks are taken into account. A negative sign indicates net increase while a positive sign indicates net decrease in stocks.
<b>Total</b>	under primary supply, 'total' is the addition of columns to obtain total availability. Under transformation, 'total' is the addition of columns to obtain transformation and conversion losses.
<b>Gas Plants (9)</b>	shows the input of natural gas into the LNG, MDS and GPP-LPG plants and their respective outputs.
<b>Refineries (10), power stations and Co-generation &amp; Private licensees (11)</b>	shows the input of any energy product (negative sign) for the purpose of converting it to one or more secondary products (positive sign).
<b>Losses and own use (12)</b>	refers to losses of electrical energy and natural gas which occur outside the utilities and plants (i.e. distribution losses) and the consumption of energy by utilities and plants for operating their installation (i.e. electricity for operating auxiliary equipment and petroleum products used in the crude distillation process respectively). It does not, however, include conversion loss that is accounted for in the 'total' column.
<b>Secondary supply (14)</b>	refers to the supply of energy from the transformation process and after deducting the energy sector's own use and losses, including power station use.
<b>Residential and commercial (15 &amp; 16)</b>	not only refers to energy used within households and commercial establishments but includes government buildings and institutions.
<b>Industrial (17)</b>	is a very broad-based sector ranging from manufacturing to mining and construction. Diesel sales through distributors are assumed to be to industrial consumers.
<b>Transport (18)</b>	basically refers to all sales of motor gasoline and diesel from service stations and sales of aviation fuel. It also includes diesel and motor gasoline sold directly to government and military.
<b>Agriculture (19)</b>	covers agriculture, forestry and fishing.
<b>Non-energy use (20)</b>	use of products resulting from the transformation process for non-energy purpose (i.e. bitumen/lubricants, asphalt/greases) and use of energy products (such as natural gas) as industrial feed stocks.
<b>Final use (21)</b>	refer to the quantity of energy of all kinds delivered to the final user.

I) Non-commercial energy such as firewood and other biomass fuels have been excluded in the energy balance until more reliable data are made available.

II) The output side of the final user's equipment of device i.e. useful energy, will not be dealt with in the balance as it will involve assessing the efficiencies of end-use equipment operating under various different conditions.

## Notes on Electricity

<b>Reserve Margin</b>	Total capacity margin is defined as the amount of installed generation available over and above system peak load  Reserve Margin = $\frac{\text{Installed Capacity} - \text{Peak Demand}}{\text{Peak Demand}}$
<b>Peak Demand</b>	The maximum power demand registered by a customer or a group of customers or a system in a stated period of time such as a month or a year. The value may be the maximum instantaneous load or more usually, the average load over a designated interval of time, such as half an hour and is normally stated in kilowatts or megawatts.
<b>Installed Capacity</b>	Installed capacity is defined as the maximum possible capacity (nameplate rating) that can be provided by the plant.
<b>Dependable Capacity</b>	The maximum capacity, modified for ambient limitations for a specified period of time, such as a month or a season.
<b>Available Capacity</b>	Available capacity refers to the Latest Tested Net Capacity. It is the dependable capacity, modified for equipment limitation at any time.
<b>Unit Generated (Gross Generation)</b>	The total amount of electric energy produced by generating units and measured at the generating terminal in kilowatt-hours (kWh) or megawatt hours (MWh).
<b>Unit Sent Out From Station(s) (Net Generation)</b>	The amount of gross generation less the electrical energy consumed at the generating station(s) for station service or auxiliaries.

## Notes on Coal

<b>Measured Resources</b>	Refers to coal for which estimates of the rank and quantity have been computed to a high degree of geologic assurance, from sample analyses and measurements from closely spaced and geologically well known sample sites.
<b>Indicated Resources</b>	Refers to coal for which estimates of the rank, quality, and quantity have been computed to a moderate degree of geologic assurance, partly from sample analyses and measurements and partly from reasonable geologic projections.
<b>Inferred Resources</b>	Refers to coal of a low degree of geologic assurance in unexplored extensions of demonstrated resources for which estimates of the quality and size are based on geologic evidence and projection. Quantitative estimates are based on broad knowledge of the geologic character of the bed or region where few measurements or sampling points are available and on assumed continuation from demonstrated coal for which there is geologic evidence.

## Notes on GDP

<b>Definition</b>	GDP is a measure of the total value of production of all resident producing units of a country in a specified period, before deducting allowances for consumption of fixed capital. A producing unit is considered as resident in a country if it maintains a centre of economic interest in the economic territory of that country. The economic territory of a country consists of the geographic territory administered by a government within which persons, goods and capital circulate freely. GDP can be measured in three but equivalent ways, namely, the sum of value added, the sum of final expenditures and the sum of incomes. In Malaysia, Department of Statistics Malaysia (DOSM) compiles annual GDP estimates using the sum of value added and sum of final expenditure approaches.
	The sum of value added (or production) based GDP is the sum of the differences between the values of the gross output of resident producing units measured in producers' values and the values of their intermediate consumption measured in purchasers' values plus import duties. The difference between gross output and intermediate consumption is value added. This approach shows the contribution of individual economic activities to the total GDP.
<b>Measuring GDP</b>	Income based estimates – summing up the incomes generated (i.e salaries and wages, gross operating surplus of enterprises and mixed income generated by households that engage in production)
	The sum of final expenditures (expenditure) approach is to sum up the expenditure values of the final users of goods and services measured in purchasers' values, less the c.i.f. values of the import of goods and services. It is calculated by estimating the values of private consumption expenditure, government consumption expenditure, gross fixed capital formation, change in stocks and exports of goods and services, less imports of goods and services. These are termed 'final demand' or 'final expenditure' categories.

## Notes on GNI

<b>Definition</b>	The Gross national income (GNI) consists of: the personal consumption expenditure, the gross private investment, the government consumption expenditures, the net income from assets abroad (net income receipts), and the gross exports of goods and services, after deducting two components: the gross imports of goods and services, and the indirect business taxes. The GNI is similar to the gross national product (GNP), except that in measuring the GNP one does not deduct the indirect business taxes.
	As GNI is an add up of Net Income from abroad and the GDP, one can calculate the GNI by the following formula:  $\text{GNI} = \text{GDP} + (\text{FL} - \text{DL}) + \text{NCI}$
<b>Measuring GNI</b>	When FL and DL are respectively the foreign and domestic income from labor, and NCI the net capital inflow. For example, if a country A's nominal GDP is \$20,000, the domestic income from labor \$3,000 and the foreign income from labor \$5,000, and the country received a \$10,000 donation from another country's charity organization, the GNI of country A would be \$32,000.

Non-Energy	6.50

# Definition

The sources of energy covered in the Energy Balances are as below:

<b>Natural Gas</b>	Is a mixture of gaseous hydrocarbons (mainly methane), which occur in either gas fields or in association with crude oil fields.
<b>LNG</b>	Is natural gas that is liquefied for ocean transportation and export.
<b>Crude Oil</b>	Is natural gas that is liquefied for extracted from mineral deposits and consists essentially of many different non-aromatic hydrocarbons (paraffinic, cyclonic, etc.).
<b>Aviation Gasoline (AV GAS)</b>	Is a special blended grade of gasoline for use in aircraft engines of the piston type. Distillation range normally falls within 30° C and 250° C.
<b>Liquefied Petroleum Gas (LPG)</b>	Commercial LPG consists essentially of a mixture of propane and butane gases which are held in the liquid state by pressure or refrigeration.
<b>Motor Gasoline (mogas)</b>	Petroleum distillate used as fuel in spark-ignition internal combustion engines. Distillation range is within 30° C and 250° C.
<b>Aviation Turbine Fuel (ATF)</b>	Fuel for use in aviation gas turbines mainly refined from kerosene. Distillation range from 150° C and 250° C.
<b>Kerosene</b>	Is a straight-run fraction from crude oil, with boiling range from 150° C to 250° C. Its main uses are for domestic lighting and cooking.
<b>Diesel (or Gas Oil)</b>	Distillation falls within 200° C and 340° C. Diesel fuel for high-speed diesel engines (i.e. automotive) is more critical of fuel quality than diesel for stationary and marine diesel engines. Marine oil usually consists of a blend of diesel oil and some residual (asphaltic) materials.
<b>Fuel Oil</b>	Heavy distillates, residues or blends of these, used as fuel for production of heat and power. Fuel oil production at the refinery is essentially a matter of selective blending of available components rather than of special processing. Fuel oil viscosities vary widely depending on the blend of distillates and residues.
<b>Non-Energy Products</b>	Refer mainly to naphtha, bitumen and lubricants, which are obtained by the refinery process from petroleum but used for non-energy purposes. Naphtha is a refined or partly refined light distillate, which is further, blended into motor gasoline or used as feedstock in the chemical industry. Bitumen is a viscous liquid or solid, non-volatile and possesses waterproofing and adhesive properties. Lubricating oil is used for lubricating purposes and has distillation range from 380° C to 500° C.
<b>Refinery Gas</b>	The gas released during the distillation of crude oil and comprises methane, ethane, propane and butane. Most refinery gas is retained in the refinery and used as fuel in plant operations.
<b>Coal and Coke</b>	Solid fuels consisting essentially of carbon, hydrogen, oxygen and sulphur. Coal in the energy balance is mainly bituminous coal (medium grade in terms of energy content) and some anthracite (high quality hard coal). Coke is obtained from coal by heating at high temperature.
<b>Hydropower</b>	Is the inferred primary energy available for electricity production and is shown in terms of conventional fossil fuel equivalent using the average thermal efficiency of conversion for the year, i.e. the hypothetical amount of fossil fuel, which would be needed to produce the same amount of electricity in existing thermal power plants.
<b>Electricity Production</b>	Production of electricity refers to production from public utilities as well as independent power producers (IPPs) and private installations & co-generation plants which obtain licenses from the Department of Electricity Supply and Market Regulation, Energy Commission. Figures for 'fuel input' into power stations & co-generation plants were only available for Tenaga Nasional Berhad, SEB, SESB, IPPs as well as GDC Sdn. Bhd. Estimations were made using average conversion efficiency to obtain the fuel input into private installations.
